MLN With FGFR1 Rearrangement Overview and Presentation

FOR MEDICAL INFORMATION PURPOSES ONLY.

MLN With *FGFR1* Rearrangement Is an Extremely Rare and Aggressive Hematologic Malignancy¹

Epidemiology

- No published estimates of incidence or prevalence
- Median age at onset is 46 years (range, 0-87 years)¹
- Slight male predominance (sex ratio, 1.2:1)^{1,2}

Clinical Course

- Aggressive natural course with poor prognosis¹⁻⁴
- May present as, or progress within 1 to 2 years to, blast phase/secondary acute leukemia^{1,3-5}
- 1-year OS after diagnosis is 43.1%¹

MLN With *FGFR1* Rearrangement Is Included in the 2016 WHO Classification of Myeloid Neoplasms and Acute Leukemia

ABL, Abelson murine leukemia; AML, acute myeloid leukemia; BCR, breakpoint cluster region; CML, chronic myeloid leukemia; JAK2, Janus Kinase 2; MDS, myelodysplastic syndrome; MPN, myeloproliferative neoplasm; NOS, not otherwise specified; PCM1, pericentriolar material 1; PDGFRA, platelet-derived growth factor receptor α; PDGFRB, platelet-derived growth factor receptor α; PDGFRB, platelet-derived growth factor receptor β; PV, polycythemia vera; RS-T, ring sideroblasts and thrombocytosis; WHO, World Health Organization. Arber D, et al. *Blood.* 2016;127:2391-2405.

Identification of MLN With *FGFR1* Rearrangement Requires High Levels of Clinical Suspicion

- Clinical phenotypes are highly heterogeneous; as such, patients may present with chronic phase or acute (blast phase) disease¹⁻³
- Patients may present asymptomatically with an incidental finding of abnormal blood counts⁴
- Eosinophilia has been noted in up to 85% of cases reported in the literature⁴

Frequencies of Reported Signs and Symptoms at Presentation⁴

^a Number of patients assessed for hepatosplenomegaly not defined.

Incyte

Dysregulation of FGFR Signaling Is Implicated in Tumorigenesis

 Aberrant FGFR signaling mediates tumorigenesis by enhancing cellular proliferation, migration, survival, invasion, and angiogenesis^{1,2}

Different genomic alterations may result in tumorigenic FGFR signaling¹:

Activating Mutations

Leading to constitutive activation of the kinase domain or ligand-independent receptor dimerization

1. Babina IS, Turner NC. Nat Rev Cancer. 2017;17:318-332. 2. Turner N, Grose R. Nat Rev Cancer. 2010;10:116-129.

Chromosomal Rearrangements

Translocations resulting in gene fusions that allow ligand-independent receptor dimerization

Gene Amplification

Inducing protein overexpression, receptor accumulation and activation of downstream signaling pathways

MLN With FGFR1 Rearrangement: Cytogenetics and Molecular Genetics

- FGFR1 rearrangements lead to the expression of aberrant tyrosine kinases¹
- Translocations at chromosome band 8p11 result in constitutive activation of *FGFR1* with the most common translocations sites including:²
 - t(8;13)(p11;q12)
 - t(8;22)(p11;q11)
- Translocations are usually identified with conventional cytogenetic analysis and can be confirmed with break-apart FISH^a

16 Currently Known Fusion Partners of FGFR1³

CP, chronic phase; ZMYM2, zinc finger MYM-type containing 2.

^a FGFR1 is NOT part of standard testing panels and must be specifically ordered.

1. Babina IS, Turner N. Nat Rev Cancer. 2017;17:318-332. 2. Jackson CC, et al. Hum Pathol. 2010;41:461-476. 3. Reiter A, Gotlib J. Blood. 2017;129:704-714

Summary

- MLN with FGFR1 rearrangement is an aggressive hematologic malignancy with poor prognosis¹
 1-year OS after diagnosis is 43.1%¹
- Diagnosis is challenging, with highly heterogeneous clinical phenotypes^{2,3,4}
 - Patients may present with chronic phase disease, acute (blast phase) disease, or asymptomatically^{2,3,4}
 - Evaluation of hypereosinophilia, often associated with myeloid and/or lymphoid neoplasms, can help facilitate a diagnosis⁵
- FGFR1 rearrangements can lead to fusions with 16 known genes, leading to aberrant expression of tyrosine kinases^{2,6}
 - -ZMYM2 and BCR are the most common fusion partners²
